

Santos QNT Pty Ltd

EP161 – HFS EMP Annual Groundwater Monitoring Data Review

14 December 2023 - Final

1. Introduction

Santos is the operator of Exploration Permit 161 (EP161) in the Northern Territory, Australia. EP161 is the subject of shale gas exploration targeting formations of the Beetaloo Sub-basin and is located approximately 120 km east of Daly Waters on the Carpentaria Highway and 600 km south-east of Darwin.

The Santos *Environment Management Plan: McArthur Basin Hydraulic Fracturing Program NT Exploration Permit (EP) 161 (revision) STO3-8* (Santos, 2021) (the HFS EMP) was approved on 6 October 2021. The scope of the HFS EMP was for hydraulic fracture stimulation and production testing of wells at the Tanumbirini and Inacumba sites (the regulated activities) (**Error! Reference source not found.**).

This report satisfies Condition 5 of the approval which requires:

An interpretative report of groundwater quality based on the groundwater monitoring required to be conducted at the well site(s) in accordance with Table 6 of the Code. The interpretative report must be provided annually within three months of the anniversary of the approval date of the EMP and include:

- Identification of any change to groundwater quality or level attributable to conduct of the regulated activity at the well site(s) and discussion of the significance and cause of any such observed change;
- Interpretation of any statistical outliers observed from baseline measured values for each of the analytes;
- Discussion of any trends observed;
- A summary of the results inclusive of descriptive statistics; and
- A description of the layout of groundwater monitoring bores and wells, indicative groundwater flow directions and levels in accordance with the Preliminary Guideline Groundwater Monitoring Bores for Exploration Petroleum Wells in the Beetaloo Sub-basin.

The Code is in reference to the *Code of Practice: Onshore petroleum activities in the Northern Territory* (DENR, 2019). It is referred to as the "Code" throughout this report. The *Preliminary Guideline Groundwater Monitoring Bores for Exploration Petroleum Wells in the Beetaloo Sub-basin* (DENR, 2018) is referred to as the "Guideline" throughout this report.

In summary, the interpretation and discussion of the observed outliers and trends identifies:

- This report includes all monitoring data acquired up to and including October 2023.
- Water levels in the control monitoring bore (CMB) and impact monitoring bore (IMB) remain within the range of background variability following execution of the regulated activities at the Tanumbirini site.
- There has been no impact to the beneficial use of the Gum Ridge Formation aquifer with respect to Livestock drinking water following execution of the regulated activities.
- There was a statistically significant increase in the dissolved methane concentration in the IMB during execution of the authorised activities, but the concentration has subsequently decreased. The dissolved methane concentration increased in the CMB from a starting concentration of less than the laboratory limit of reporting. It decreased to less than the limit of reporting but has again been detected in the three most recent results. The maximum reported dissolved methane concentration (48 µg/L in the IMB) at the Tanumbirini well site is an order of magnitude less than maximum concentration observed in pastoral

bores elsewhere on Tanumbirini Station. The absence of propane and ethane is indicative that the methane is most likely not thermogenic in origin and therefore unlikely to come from the reservoir via the exploration wells. CSIRO has previously identified that dissolved methane in the Gum Ridge Formation – the same aquifer as the CMB and IMB – is biogenic methane.

- Changes in major ion and trace element chemistry and the temperature response in the IMB are indicative of a subtle influence of the drilling process on the groundwater quality. Similar changes were observed following the drilling of the CMB and IMB. No influence of the hydraulic fracture stimulation was observed.
- No drilling activities or fracture stimulation activities have been performed at the Inacumba site.
- Rising trends have been observed in pH and other analyte concentrations at the Inacumba site however no regulated activities have been commenced by Santos at this site.
- There is a small but consistent correlation between analysed batches of samples and trace parameter concentrations across all results. This is expected where all analyte concentrations are extremely low. The correlation represents the variability in measurement accuracy which is consistent between batches of samples analysed by the laboratory.

2. Exploration activities

The locations of Santos activities on EP161 are shown on Figure 1.

Santos drilled the Tanumbirini 2H and Tanumbirini 3H exploration wells between May and November 2021. 'Tanumbirini 2' and 'Tanumbirini 3' are used throughout this report to refer to the vertical wells and their associated horizontals. Key dates associated with the drilling activities are summarised in Table 1, and are shown on Figure 2 and on the graphs in Attachment C.

The wells were drilled using mud rotary methods. The wells were initially drilled using water-based drilling fluids (mud) until lost circulation was encountered in the Cambrian Limestone Aquifer. At this point the drilling fluid was swapped to bore water with no drilling additives until the aquifer had been sealed off from the well. Water for drilling was sourced from RN040930, the CMB at the Tanumbirini site.

The wells underwent hydraulic fracture stimulation (HFS) in December 2021, flowback commenced immediately thereafter and continued to December 2022, when the wells were shut-in and remote monitoring commenced. Hydraulic fracture stimulation of the wells was approved under *McArthur Basin Hydraulic Fracturing Program NT Exploration Permit (EP) 161 STO3-8* (HFS EMP).

No drilling or hydraulic fracturing activities have been performed at the Inacumba site to date. Monitoring bores were installed at the Inacumba site in 2018 and 2019.

Santos has installed groundwater monitoring bores at the Jibera South and Inacumba South locations. No exploration activities have been approved or performed at these locations.

Date	Event
11-May-21	Tanumbirini 2H start drilling (spud)
17-Aug-21	Tanumbirini 2H complete drilling (rig release)*
23-Aug-21	Tanumbirini 3H start drilling (spud)
19-Nov-21	Tanumbirini 3H complete drilling (rig release)*
1-Dec-2021	Hydraulic fracture stimulation (frac) start
19-Dec-2021	Hydraulic fracture stimulation end
19-Dec-2021	Flowback start
3-Dec-2022	Flowback end. Remote monitoring starts.

Table 1 Key dates of the EP161 exploration activities at Tanumbirini

* drilling and well construction would have been completed several days prior to rig release

Figure 1 Activity and monitoring bore locations

Beetaloo_FracEMP.qgz|Activities and Bore Locations

3. Tanumbirini

This review focusses on the groundwater monitoring data acquired during the regulated activities performed on the Tanumbirini 2 and Tanumbirini 3 exploration wells. Data from prior to May 2021, when drilling commenced, was used to establish baseline groundwater conditions.

Monitoring Activities

In December 2018 and in accordance with the Guideline a control monitoring bore (RN040930 – 43 m from Tanumbirini 2) was installed at the Tanumbirini site, and the impact monitoring bore (RN040936 – 16 m from Tanumbirini 3) was installed in July 2019. Water level contours for the GRF were prepared using data collected by Santos (RDM Hydro, 2021) and indicate groundwater flow directions in the vicinity of Tanumbirini are from east-southeast to west-northwest (Figure 1). Both bores are installed to enable monitoring of the full thickness of the Gum Ridge Formation (GRF). The Anthony Lagoon Formation aquifer is not present at the Tanumbirini well pad.

Water level, temperature and conductivity (LTC) sensors were installed in the monitoring bores in September 2020 (prior to the approval of the Drilling EMP), replacing the previously installed sensors. A barometric pressure sensor was also installed at the site at this time. During background monitoring the sensors record every four hours. Condition 6 of the HFS EMP approval required *groundwater level/pressure monitoring at each impact monitoring bore established, using a logger to record water level for 2 weeks prior to, during, and 4 weeks after completion of hydraulic fracturing operations at each well pad. Data logging should record at a minimum of every 4 minutes for the duration of the recording period. Accordingly, the datalogger, the recording interval in RN040930 and RN040936 was increased to four minutes from 29 September 2021 (62 days prior to the start of the HFS) to 2 February 2022 (45 days after the end of the HFS activity). It was then returned to a four-hourly recording interval. The original LTC logger failed in October 2022 and was replaced in January 2023. No logger data is available for the intervening period.*

RN040930 was equipped with a dedicated electric submersible pump which is used for purging and sampling, at a pumping rate of 17 L/s. This bore was used for water supply throughout the regulated activities. The pump was replaced with a lower capacity sampling pump in December 2022.

RN040936 was constructed with sealed sub-surface headworks in a "gatic" in accordance with the Bore Work Permit. Prior to the commencement of the 2021 drilling program, an electric submersible pump was installed in the bore to allow baseline water quality monitoring. Because of its close proximity to the exploration wells (16 m from Tanumbirini 3, in accordance with the Guideline) and to allow the drill rig to operate, the pump was removed from the bore and the headworks sealed, therefore water quality monitoring could not be undertaken during drilling activities. The LTC sensor remained in the bore for the duration of the drilling campaign. The sampling pump was reinstalled during rig-down (at the end of drilling) and prior to the commencement of HFS activities and has remained available for sampling since.

Routine water quality monitoring of the bores commenced in July 2019. The suite of analysis is compliant with Table 6 of the Code and exceeds the requirements of the Guideline. RN040930 had been monitored 27 times and RN040936 had been monitored 10 times prior to the commencement of drilling in 2021. RN040930 has continued to be monitored for water quality at a quarterly interval. RN040936 was monitored on 16 March 2021, approximately 1 month before the drilling rig mobilised to site, and quarterly monitoring recommenced on 17 November 2021, after the completion of drilling of Tanumbirini 3, but prior to the HFS. Quarterly monitoring has continued through 2022 and 2023. A sample could not be collected from RN040930 in January 2023 due to a pumping equipment failure, however a sample was collected in February 2023 during a return visit. Twelve samples have been collected from RN040930 and ten samples have been collected from RN040936 (two on the same day) since the start of the regulated activities.

Water level, temperature and electrical conductivity monitoring

The timing of sampling relative to exploration activities can be seen on Figure 2. The downhole sensor responses are described and interpreted as follows.

RN040930 (CMB)

- Groundwater extraction for water supply from RN040930 started on 6 April 2021. Extraction was initially
 during daytime hours only until the commencement of Tanumbirini 2 drilling. The frequency then reduced
 and become more intermittent. Extraction increased to fill storages prior to the HFS. During the HFS,
 extraction was effectively continuous. There has been infrequent, short-duration extraction only since
 the completion of the HFS in late December 2021.
- There are diurnal water level fluctuations of 2 mm to 12 mm in RN040930 due to barometric pressures changes.
- A water level drawdown of approximately 0.05 m (5 cm) was recorded within the bore during pumping of RN040930.
- There was a long-term *rising* trend of 0.2 m over the period of extraction, which appeared to cease approximately a month after extraction ceased and then stabilised. Water levels have more recently started to decline. This is roughly consistent with regional water level trends as observed in NTG monitoring bores (accessed via the Water Monitoring Portal) screened in the Cambrian Limestone Aquifer around the Beetaloo Basin. These trends are shown on Figure 3. The most recently available data from the Water Monitoring Portal for these bores was from May 2023.
- The logger failed in October 2022 and was replaced in January 2023. There is no logger data available from the intervening period. The Guideline does not mandate the use of water level and conductivity sensors.
- There was a rise in temperature of 0.2 °C during extraction, followed by a longer-term rise in the overall water temperature. Following extraction the temperature stabilised and then declined very gradually. The increased temperature indicates that the extracted groundwater is potentially coming from deeper in the bore than the sensor and pump intake (roughly 130m below ground). The increase in temperature in October 2022 is likely an artefact due to the replacement sensor being installed marginally deeper than the original sensor.
- The EC showed a correlation to the amount of pumping, with EC increasing in proportion to the amount of extraction. This may relate to differential depressurisation of discrete fractures within the limestone, and a change in the relative proportion of water provided by each fracture to the bore. The drop in the logger EC between October 2022 to January 2023 is related to a different calibration of the replacement sensor.

RN040936 (IMB)

- The overall water level response was similar to RN040930, but the overall rising trend was smaller, with a maximum increase of less than 0.05 m (5 cm). The water level returned to the pre-activity water level in about June 2023 and has been relatively stable since.
- The influence of ongoing extraction over approximately 2 months can be seen as a small (~1 cm) decline in water level.
- Shortly after the start of drilling of Tanumbirini 2, there was a drop in water level, much like if the bore were being pumped (which lasted about a day), and then a flat signal.
- A small decrease in temperature (<0.05 °C) after the start of drilling of Tanumbirini 2 and a declining temperature after the start of drilling of Tanumbirini 3. These changes in temperature may be related to the influence of drilling fluids which were cooler than the aquifer water due to the former being stored on the surface.
- Step changes in the temperature response are due to changes in the logger depth. These changes are only 0.4 °C in total.
- The temperature and electrical conductivity in RN040936 are subtly affected by pumping in RN040930.

• There is a small (~1 cm) seasonal influence of barometric pressure on the water level trend.

Water quality monitoring

For each of RN040930 and RN040936, Attachment A includes a summary table that contains:

- A statistical summary of all groundwater quality results,
- The results of samples collected immediately prior to and after the start of drilling, and
- The P-value of the T-Test comparing the analyte results from pre the start of drilling and post the start of drilling.

A Before After/Control Impact (BACI) approach has been used to assess the potential effects of drilling activities on groundwater quality.

Gross alpha is the only parameter that exceeded its ANZECC (2000) livestock drinking water guideline value. It was exceeded in both the RN040930 and RN040936 including baseline water quality. Therefore, this exceedance is not related to drilling activities. Gross beta activity also exceeded the ANZECC (2000) livestock drinking water guideline value in one baseline water quality result from RN040930.

The groundwater quality results have been graphically presented as box-and-whisker plots (Attachment B). The statistics were calculated on all data up to and including 16 March 2021 (baseline data – prior to the start of drilling), with those results from samples collected post 16 March 2021 shown as individual symbols. The boxand-whisker plots were used to identify those parameters which exceeded the range of background variability in at least one sample. Where a parameter was identified to exceed the range of background variability, a timeseries chart was prepared (Attachment C), with results from other sites where Santos has installed monitoring bores provided for comparison (control sites). The timeseries charts for a parameter are scaled based on the maximum concentration across all of the sites. The trends identified in these charts are described in Table 2.

The timeseries charts mostly show no consistent trend in parameter concentrations. In some cases the baseline maximum is exceeded in the first sample collected after the drilling commenced, others the middle or the last. Sometimes the concentrations have decreased to less than the baseline maximum by the end of drilling. There appears to be correlations in the many of the parameter concentrations across all of the monitoring sites. This is most likely related to laboratory measurement uncertainties rather than changes in the aquifer as the monitoring bores are separated by distances of 10-20 km and show the same variations in concentrations. Laboratory measurement uncertainties are greatest when the concentrations are less than ten times the limit of reporting (i.e. the values are very low concentrations).

Since there is bias in the selection of the pre-activity maximum concentration, a statistical assessment was made using a Student T-Test to test whether there was a significant difference in the results before and after the start of exploration activities on Tanumbirini 2 and Tanumbirini 3. An F-Test was used to determine whether the homoscedastic (statistically similar variance) or heteroscedastic (statistically different variance) formula for the T-Test was used. Where a concentration was reported as less than the limit of reporting, the limit of reporting was assumed to be the sample concentration. The statistical significance was assessed to a 95% confidence. The results of the analysis are included in the statistical summaries in Attachment A. The bores and parameters where the P-value was less 0.05 (95% confidence that there is a significant different between the pre- and post-drilling data) are identified in Table 3. The parameters identified are generally consistent with those in which the maximum baseline concentration was exceeded. For some of the trace elements (metals/metalloids), there was a statistically significant *decrease* in the reported concentration, i.e. water quality improved following exploration activities, as identified in Table 3.

The observed variability in major ion and trace element concentrations suggest a possible, but subtle, influence of the exploration activities on the groundwater quality in the vicinity of the wells. This influence is likely to be related to the drilling of the wells through the following mechanisms:

- **Drilling mud**: there were increases in potential indicators of the presence of drilling mud such as potassium, chloride, pH, alkalinity and barium.
- **Drill cuttings**: Mobilisation of ions and elements associated with the increased surface area of the cuttings relative to in-tact formation, and through the oxidation of the minerals from the oxygen rich drilling mud that had been stored in open tanks on surface. Wallis and Pichler (2018) and Poulsen et al. (2020) refer to these mechanisms in the literature. A similar influence on water chemistry could be seen in the evolution of the baseline water chemistry observed in most of the monitoring bores where declining trends in parameters were observed following drilling of the water bore itself, until a relatively stable baseline had been reached (RDM Hydro, 2022).

There were no significant changes to the groundwater chemistry that can be attributed to the regulated activities.

Figure 3 Regional groundwater level monitoring of the Cambrian Limestone Aquifer

RDM

Table 2 Tanumbirini - Description of trends in parameters exceeding the baseline maximum concentration

Parameter (and fraction) exceeding baseline range in natural variability	Bore(s) in which exceedances were reported	Description
pH - Lab		The laboratory pH measured in all three bores at Tanumbirini (CMB, IMB and RN038580) was reported to increase during both drilling and HFS activities, but then declined in February 2021 to withi 7.9 in May 2022, dropping again in July 2022, and then rising again. Since December 2022, the pH in all bores with pumps still installed has decreased to their reported minima. Similar trends in pH were observed across the other Santos monitoring sites.
Chloride		Both the CMB and IMB chloride concentrations increased marginally during activities and exceeded their pre-activity maxima, and then varied around the pre-activity average, with the most recent s for these bores (106 mg/L and 107 mg/L). The chloride concentration in RN038580 rose very slightly after the start of drilling but declined to less than the pre-activity concentrations after the start of the flowback but has increased again and Chloride results from Jibera South, Inacumba and Inacumba show similar trends across all aquifers for the earlier data, but pumps have bee removed from most of these bores. The recent data for F observed from Tanumbirini.
Sodium		The sodium concentration remained consistent in the CMB and IMB throughout the drilling and first six months of flowback. In July 2022 there was a slight rise in the sodium concentration in both the slightly higher through the second half of 2022 but declined through 2023 for final concentrations of ~75 mg/L, marginally less than the pre-activity values. Similar rising trends in sodium concentrations are observed in the results from results from Jibera South, Inacumba and Inacumba South prior to pump removal. The chloride content in RN041242 d
Potassium		Potassium concentrations in the CMB increased to its maximum reported value in the first sample after the start of drilling, but then deceased to within the background range, although on a slight ris rising trend through the drilling and HFS activities. The potassium concentration in both bores decreased in the first two samples following the HFS but show an upward trend in the two subsequent 2023. Samples from the other sites and all aquifers show similar rising trends through 2022, with the most recent data from RN041242 showing similar declining trends to the bores at Tanumbirini through
Calcium		Calcium concentrations effectively remain consistent in both the CMB and IMB from once the bore chemistry stabilised after drilling and through the drilling activities. Consistent with calcium concent Inacumba South), calcium concentrations were reported to decrease from after the start of the flowback, prior to increasing from May 2022 to greater than the pre-activity maxima. Since October 202 than the concentrations reported pre-activity. A similarly declining trend is observed in the data from RN041242, although its most recent calcium concentration is similar, rather than less than, its ini
Magnesium		The magnesium concentrations in the IMB, CMB and RN038580 reported effectively flat trends following the establishment of baseline conditions in Q1 2019 and very slightly declining trends from the October 2022 samples reported relatively higher concentrations in all Santos monitoring bores, with the IMB exceeding its pre-activity maximum (60 mg/L compared with 59 mg/L). Concentrations in pre-activity maxima. Relatively greater concentrations were reported from the other Santos sites in October 2022. While most bores have not been sampled since October 2022, the concentration in
Methane (dissolved)	RN040930 (CMB) RN040936 (IMB)	Dissolved methane concentrations in the IMB reported steadily declining trends from the peak in February 2022 of 48 µg/L to January 2023 (15 µg/L), however in May 2023 the reported concentration µg/L, which is comparable to a pre-activity maximum concentration of 9 µg/L. The CMB dissolved methane concentrations have always been less than the IMB but have shown similar trends. The methane RN038580 reported dissolved low methane concentrations prior to the commencement activities. Prior to the activities, the CMB had previously only reported concentrations <lor. (during="" (october="" (the="" 2="" 2019="" 2021="" 2022="" 2023="" 2023)="" 37="" 4="" 6="" <lor="" <lor.<="" a="" activities)="" activities,="" again="" an="" and="" august="" been="" concentration="" concentrations="" concentrations.="" declining="" drilling="" exploration="" from="" have="" in="" increase="" january="" july="" l="" l.="" local="" methane="" mg="" minimum="" monitoring="" most="" no="" november="" of="" or="" other="" peak="" recent="" results="" rising="" rn038580="" rn040938="" sample).="" samples="" santos="" show="" showed="" sites,="" td="" the="" there="" thereafter="" through="" to="" trend="" variable="" were="" where="" µg=""></lor.>
Boron (dissolved)		The CMB reported a maximum concentration (0.21 mg/L) in the first sample following the start of drilling, as compared with its pre-activity maximum of 0.19 mg/L. The concentration decreased to 0. increasing again to 0.2 mg/L in February 2022. Through 2022, the concentration gradually decreased, but started to increase again in 2023, reaching 0.22 mg/L in May 2023, but reporting decreasing 2023 (0.11 mg/L). In the IMB, the pre-activity maximum reported boron concentration was 0.19 mg/L. The dissolved boron trend in the IMB was similar to the CMB, with the IMB reporting a maximum 0.13 mg/L in October 2023 (most recent sample) In RN038580, the dissolved boron concentration decreased from a pre-activity maximum of 0.19 mg/L to 0.13 mg/L in February 2022, but increased to follow the same trends as the CMB and IMB fr All of the Santos monitoring bores show similar trends in concentrations to the bores at the Tanumbirini site. RN040931, at Inacumba, reported concentrations of dissolved bore greater than 0.2 mg/ from the bore.
Copper (dissolved)		Following stabilisation of background concentrations (after December 2019) the dissolved copper concentrations were <lor (0.001="" (0.004="" (december="" 202="" <="LOR.<br" <lor,="" a="" after="" and="" cmb="" concentration="" concentrations="" copper="" dissolved="" drilling="" end="" except="" first="" for="" had="" imb="" imb.="" in="" l)="" l).="" maximum="" may="" mg="" of="" previously="" reported="" reporting="" rn038580="" sample="" samples,="" since="" the="" those="" were="">Dissolved copper concentrations from the other Santos monitoring bores are generally <lor, concentrations="" however="">LOR have been reported.</lor,></lor>
Lithium (dissolved)		The CMB (0.084 mg/L) and IMB (0.078 mg/L) reported dissolved lithium concentrations greater than their historical maxima in May and February 2023 respectively. Concentrations have since declir respectively in October 2023, which are similar to their initial concentrations. RN041242 concentrations show similar trends to the Tanumbirini bores. The Dissolved lithium concentration from RN040931 was generally greater than 0.4 mg/L
Strontium (dissolved)	•	The dissolved strontium concentrations in the CMB and IMB have generally moved in concert, decline from roughly 0.8 mg/L pre-drilling, and gradually rising to a local maximum of 0.82 mg/L in Jan the CMB and IMB through 2022, but bore bores reported maximum concentrations in May 2023 (CMB = 0.905 mg/L, IMB = 0.861 mg/L), but declining to less than 0.8 mg/L in July and October 2023 Similar trends are observed from the other Santos monitoring bores where there have been no exploration activities. The dissolved strontium concentration in RN040931 was consistently less than 0. October 2021.
Boron (total)		The CMB reported a total boron concentration (0.27 mg/L) during the drilling of Tanumbirini 2 exceeding its pre-activity maximum (0.22 mg/L) in August 2021. The concentration decreased to 0.16 m 0.2 mg/L in February 2022 and then declining to 0.14 mg/L in October 2022, but rising to 0.18 mg/L in January 2023. The IMB total boron concentration showed a declining trend through the activities to January 2021, but then increased to its maximum reported concentration (0.28 mg/L) in July 2022. The concentration mg/L in January 2023. Through 2023, the total boron concentrations in the CMB and IMB have moved in concert, with the final samples (October 2023) reporting 0.17 mg/L and 0.15 mg/L for the CMB and IMB respectivel RN038580 reported total boron concentration in February 2022 (0.21 mg/L) that exceeded its pre-activity maximum (0.19 mg/L). The concentration then declined but increased again to 0.21 mg/L in Total boron concentrations in the other Santos monitoring bores show similar variability in trends across the bores and site.
Copper (total)	RN040930 (CMB)	The total copper concentration in the CMB peaked at 0.031 mg/L in the last sample prior to drilling and exhibited a declining trend during the drilling and HFS program. The concentration was <lor 0.043mg="" 2022="" <~lor="" and="" in="" l="" october="" reduced="" reported="" since.<br="" to="" was="">Total copper concentrations in other monitoring bores have generally been <lor, (lor)="" 2022="" concentrations="" except="" in="" low="" october="" reported.<="" td="" very="" were="" when=""></lor,></lor>
Electrical conductivity at 25°C		The electrical conductivity (EC) of the groundwater in the Gum Ridge Formation at the Tanumbirini site is approximately 1,300 μ S/cm, with the three bores showing slight variations over time, general the IMB was 1,360 μ S/cm, as compared with its maximum prior to the start of activities of 1,340 μ S/cm and minimum of 1,280 μ S/cm. The most recent concentration has decreased to 1,260 μ S/cm. to activities starting, and 1,390 μ S/cm during activities. The most recent EC was 1,280 μ S/cm. Bores at other sites also reported slight variations in EC over time and in concert with each other suggesting potential variations in the laboratory sensor calibrations
Total Dissolved Solids @180°C	RN040936 (IMB)	The TDS concentrations reported from the IMB have mostly varied in concert with the CMB. The maximum reported pre-activity TDS from the IMB was 878 mg/L, with a maximum concentration of 9 drilling in November 2021. The reported TDS from the IMB decreased to 826 mg/L after the completion of the HFS (July 2022), but increased in the two samples since (October 2022 and January 24 declined during 2023, but increased slightly in the final sample to 869 mg/L. The October 2023 concentration in the CMB was 840 mg/L TDS and generally shows a similar trend to the IMB. The most recent concentration (February 2023) in RN038580 was 877 mg/L TDS and shows a similar trend to the CMB and IMB.

ithin the range of background variability before increasing to ~pH t samples reporting concentrations amongst the lowest reported nd followed the same trend as the CMB and IMB. or RN041242 at Inacumba shows similar trends to those the CMB and IMB, with the sodium concentration remaining declined during 2023, similar to Tanumbirini. rising trend to the end of the HFS. The IMB showed a similar ent samples, followed by more recent declining trends through gh 2023. centrations from the other sites (Jibera South, Inacumba and 2022 calcium concentrations have declined to ~125 mg/L, less initial concentration. m the start of drilling through to the July 2022 samples. The have since declined in both he IMB and CMB to less than the in RN0421242 has also declined (similar to Tanumbirini). ation increased to 25 µg/L, but has subsequently declined to 10 e most recent CMB concentration was reported as 4 µg/L, on slowly increased to 6 mg/L in May 2022, prior to declining f 37 µg/L, followed by a decrease over 6 months to 10 µg/L. All 0.19 mg/L (May 2021) and 0.18 mg/L (November 2021) before asing concentrations from July 2023 (0.18 mg/L) and October num concentration of 0.2 mg/L in May 2023, before declining to B from May 2022. ng/L from September 2020 onward, until the pump was removed nber 2021) reported the presence of dissolved copper in both the 2022 of 0.014 mg/L. clined to 0.069 mg/L and 0.071 mg/L from the CMB and IMB anuary 2021. There was some variability in the trends between 023. an 0.2 mg/L from January 2020 to the last sample collected in 6 mg/L in November 2021 (prior to HFS) but increased again to ntration decreased to 0.17 mg/L in October 2022 but rose to 0.21 ively. in January 2023. No samples have been collected since. OR in May 2022, but then spiked up to 0.16 mg/L in July 2022, nerally in concert with each other. The maximum reported EC in m. The maximum reported EC in the CMB was 1,410 µS/cm prior

of 920 mg/L reported from the first sample collected following y 2023) with the last sample reporting a TDS of 916 mg/L. IT

Parameter (and fraction) exceeding baseline range in natural variability	Bore(s) in which exceedances were reported	Description
2		The concentration in RN041242 shows a similar trend to the IMB and CMB.
Bicarbonate Alkalinity as CaCO3		The dominant major anion in the groundwater in the Gum Ridge Formation is bicarbonate. The maximum bicarbonate concentration in the IMB (435 mg/L) was reported from the November 2021 sam bicarbonate concentration decreased to a minimum post-activity concentration of 377 mg/L in May 2022, but then increased to 419 mg/L in July 2023, with an October 2023 reported concentration of Concentrations in the other Santos monitoring bores show similar temporal trends. The most recent (October 2023) concentration in the CMB was 400 mg/L.
Nitrate		The nitrate concentration in the IMB and CMB was <=LOR prior to and through the activities at Tanumbirini. The IMB sample from May 2023 reported 0.09 mg/L and has since declined to <lor. <lor,="" and="" are="" at="" bores="" concentrations="" consis<="" except="" for="" generally="" in="" inacumba="" jibera="" low="" monitoring="" nitrate="" of="" other="" rn040932="" rn040937="" santos="" south="" south,="" td="" were="" where=""></lor.>
Nitrite		The nitrate concentration in the IMB and CMB was <lor 0.13="" 2023="" <lor="" <lor.="" activities="" all="" and="" at="" bores="" concentrations="" declined="" for="" from="" has="" imb="" in="" l="" may="" mg="" monitoring="" nitrite="" other="" prior="" reported="" results.<="" sample="" santos="" since="" tanumbirini.="" td="" the="" through="" to="" were=""></lor>
Reactive Silica		The reactive silica concentration in the IMB exhibited a very slight rising trend from 22.9 mg/L in March 2021 to 25.1 mg/L October 2022. It reported decreasing concentrations through 2023, with a fin maximum pre-activity concentration was 24.9 mg/L. The CMB reported similar concentrations and trends from the end of the HFS. Reactive silica concentrations show more variability between the Santos monitoring bores than most other parameters.
Gross alpha		The pre-activity maximum reported Gross alpha concentration in the IMB was 0.82 Bq/L with a local maximum concentration (0.93 Bq/L) reported in July 2022. The concentration in the IMB then reduce 2023 to 1 Bq/L in October 2023. The CMB reported an increased concentration during drilling to a maximum of 0.91 Bq/L in August 2021, but the decreased and changing in concert with the IMB and RN041242 since. The most rece Gross alpha shows some variability in reported concentration magnitude in all monitored bores, with the direction of change mimicking those reported from the IMB.
Gross beta		The gross beta concentration in the IMB reported a declining trend from a 0.39 Bq/L peak in July 2020 (prior to the start of drilling) to 0.24 Bq/L in November 2021, after the completion of the drilling at 2022) the concentration increased to 0.36 Bq/L, decreased to 0.31 Bq/L in May 2022 and then increased to its reported maximum of 0.44 Bq/L in July 2022 prior to declining to 0.34 mg/L in October 20 most recent sample (October 2023) reporting a concentration of 0.29 Bq/L. Gross beta concentrations show some consistencies in concentration trends between the monitoring bores but are less correlated than many of the other parameters where this occurs.
Aluminium (dissolved)	-	The dissolved aluminium concentration in the IMB has historically been <lor. 0.02="" 2023="" also="" and="" as="" cmb="" concentrations="" from="" l.="" may="" mg="" reported="" result="" rn041242="" the="" was="">LOR from each of the CMB and RN038580, all reported dissolved aluminium concentrations were <lor.< td=""></lor.<></lor.>
Barium (dissolved)		The pre-activity maximum reported concentration of dissolved barium (0.05 mg/L) was only exceeded in the IMB (0.051 mg/L) in November 2021 declining to 0.040 mg/L in May 2022, increasing to 0.0 sample reported a concentration of 0.043 mg/L. A similar trend was reported from the CMB, reaching a maximum of 0.048 mg/L during activities compared with a pre-activity maximum of 0.05 mg/L. The most recent concentration was 0.042 mg/L in Barium is ubiquitously present in the groundwater samples collected across the Santos monitoring bores. The maximum reported dissolved barium concentration (0.137 mg/L) reported from RN04093 concentrations reported from the Tanumbirini site. Similar temporal trends are observed in the dissolved barium concentrations reported from RN041242 compared with the IMB and CMB.
Aluminium (total)		Total aluminium was reported <lor (0.01="" 0.02="" 2022="" <lor="" activities="" all="" collected="" february="" imb="" in="" l="" mg="" mg<br="" of="" one="" other="" prior="" reported="" samples="" starting.="" the="" to="" whereas="">The CMB reported total aluminium in the August 2021 sample (0.02 mg/L), but had previously had a reported concentration of 0.03 mg/L. Both the IMB and CMB have reported <=LOR since February 2022. Significantly higher dissolved aluminium concentrations have been reported from the other Santos monitoring bores, generally from the first sample collected, where the concentration may be influence here. Concentrations are presented and the first sample collected where the concentration may be influence here. Concentrations are presented and the first sample collected where the concentration may be influence here. Barium (total)	-	bore. Concentrations are generally <=LOR. In the IMB, the total barium concentration exceeded the pre-activity maximum (0.049 mg/L) in the November 2021 (0.05 mg/L) and the two samples collected in February 2022 (0.086 mg/L and 0.055 the pre-activity maximum but had a declining trend from February 2022 until July 2023 when it had a reported concentration of 0.044 mg/L, less than the pre-activity maximum. The most recent (Octob was 0.046 mg/L. The CMB reported some variability in total barium concentration through the activities (0.044-0.04 mg/L), but the concentration did not exceed the pre-activity maximum (0.049 mg/L) and showed a ma from 0.047 mg/L to 0.049 mg/L between February and October 2022. The concentration in the CMB has since declined to 0.044 mg/L (July and October 2023). Total barium concentrations are regularly greater at Jibera South and Inacumba South as compared with Tanumbirini.
Chromium (total)		Prior to activities commencing, the IMB reported total chromium <lor. 0.002="" 2021="" 2022="" 2023.<br="" <lor="" and="" chromium.="" concentration="" february="" from="" has="" in="" l="" mg="" most="" november="" october="" recent="" reduced="" reported="" sample="" the="" to="" total="">The CMB total chromium concentration was also <lor 2022="" 2023.<br="" and="" throughout="">Most other Santos monitoring bores report total chromium that fluctuate between <lor and="LOR.</td"></lor></lor></lor.>
Lithium (total)		The pre-activity maximum total lithium concentration reported from the IMB was 0.076 mg/L from May 2020. The concentration then decreased to a minimum of 0.058 mg/L in November 2020, before start of activities. Through the activities and 2022, the concentration fluctuated between 0.066 mg/L and 0.075 mg/L, mostly reported around 0.07 mg/L. The concentration rose in 2023 to a maximum recent concentration was 0.075 mg/L. A similar rising trend in the total lithium concentration from late 2022 through to May 2023 was observed in the CMB.
Molybdenum (total)		Prior to activities commencing, the IMB reported total molybdenum <lor. 0.002-0.004="" 0.003="" 2020="" 2021="" 2022="" 2023.="" <="LOR.</td" <lor="" <lor.="" a="" at="" bore.="" bores="" cmb="" concentration="" consistently="" declining="" drilling="" february="" from="" has="" in="" inacumba="" including="" it="" jibera="" l="" l.="" march="" mg="" molybdenum="" molybdenum.="" monitoring="" most="" november="" october="" of="" other="" post="" prior="" range="" recent="" reduced="" remained="" report="" reported="" reports="" rn040931="" rn040938="" sample="" santos="" since="" south="" stabilised="" the="" to="" total="" when=""></lor.>
Strontium (total)		The total strontium concentration in the IMB has moved in concert with the concentration in the CMB. Pre-activity maximum concentrations were reported in September 2020 (IMB 0.876 mg/L and CM in the next sample, collected in November 2020. The concentrations increased in both bores prior to the start of drilling but remained less than the pre-activity maxima. Concentrations remained relative 0.861 mg/L in the IMB/CMB respectively in February 2022. Concentrations then declined in May 2022 prior to showing an increasing trend from then to October 2022, where the IMB concentration decreases to ~0.77 mg/L. The CMB concentration show a little more variability through 2023, but also declined to similar Similar concentrations and trends in total strontium are observed across all monitoring bores.

4. Inacumba

There have been no drilling or HFS activities at Inacumba. The Inacumba site is approximately 20 km to the east of Tanumbirini.

Monitoring Activities

Monitoring activities target two formations at the Inacumba site.

Gum Ridge Formation (GRF)

A control monitoring bore (RN040931 – up hydraulic gradient of the proposed well locations) was installed in the Gum Ridge Formation (GRF) at the Inacumba site in December 2018 and a future impact monitoring bore (RN040935 – down hydraulic gradient of the proposed well locations) was installed in July 2019. Both bores are installed across the full thickness of the Gum Ridge Formation (GRF) in accordance with the Guideline.

Water level, temperature and conductivity (LTC) sensors were installed in the monitoring bores in September 2020, replacing previously installed sensors that were found to provide unreliable data. The sensors record at four hourly intervals. The LTC sensor in RN040931 was removed from the bore in December 2022. Data acquisition from the LTC sensor in RN040935 failed at the end of May 2023 and was reinstated at the end of July 2023.

RN040931 was equipped with a dedicated electric submersible pump which is used for purging and sampling, at a pumping rate of ~0.5 L/s, however the bore cannot sustain this pumping rate. Routine water quality monitoring of RN040931 commenced in late July 2019. The suite of analysis exceeds the requirements of the Guideline and is compliant with Table 6 of the Code. RN040931 has been sampled 27 times. A sample could not be collected in February 2022 as the site was not accessible due to wet weather. The pump was removed from the bore in December 2022 and the last sample available for RN040931 was collected in October 2022.

RN040935 was constructed as a future IMB with sealed sub-surface headworks in a "gatic" in accordance with the Bore Work Permit. There is no pump installed in this bore and no water quality samples have been collected.

Inacumba Aquifer (IA)

Santos, working with the NTG (Tickell, 2020), identified a previously unrecognised stratigraphic interval, informally called the Inacumba Unit. The Inacumba Unit comprises a red-brown siltstone overlying a clean limestone. The Inacumba Unit has been encountered at the Tanumbirini and Inacumba exploration sites, where it is up to ~200 m thick, but is not known further west. A control monitoring bore (RN041242) and a future impact monitoring bore (RN041243) were installed in the Inacumba Unit aquifer in September 2019.

Water level, temperature and conductivity (LTC) sensors were installed in the monitoring bores in September 2020. The sensors record at four hourly intervals. The LTC sensor in RN041243 failed in August 2022 and was replaced in January 2023. It failed again at the end of May 2023. There is no data available for the periods of failure, however manual water levels were collected.

RN041242 was equipped with a dedicated electric submersible pump which was used for purging and sampling, at a pumping rate of 17 L/s. Routine of water quality monitoring of RN041242 commenced in October 2019. The suite of analysis exceeds the requirements of the Guideline and is compliant with Table 6 of the Code. RN041242 had been sampled 11 times. A sample could not be collected in January 2022 as the site was not accessible due to wet weather. The pump was removed from the bore in December 2023 and was replaced with a smaller pump in April 2022, thus a sample was not collected in January 2023.

RN041243 was constructed as a future IMB with sealed sub-surface headworks in a "gatic" in accordance with the Bore Work Permit. There is no pump installed in this bore and no water quality samples have been collected.

Water level, temperature and electrical conductivity monitoring

The timing of sampling relative to exploration activities can be seen on Figure 2. The downhole sensor responses are described and interpreted as follows.

- There is a slight seasonal fluctuation in water level that lags behind but follows barometric pressure
- The following diurnal variations in water level (approximate) can be observed:
 - RN040931 (GRF) 0.05 m (5 cm)
 - o RN040935 (GRF) 0.025 m (2.5 cm)
 - RN042142 (IA) 0.07 m (7 cm)
 - \circ RN042143 (IA) 0.07 m (7 cm)
- There is an approximately 0.05 m decline in overall water levels in the GRF and 0.1 m decline in the IA

- The temperature and conductivity response in RN042142 indicate that pumped water is coming up the bore from deeper in the formation, and that the deeper water may be more saline than shallower water within the same geological formation. This is indicative of fracture dominated flow.
- The electrical conductivity measured by the sensor in RN040931 was roughly 250 µS/cm greater than the field measured electrical conductivity. Both sets of data show similar effectively flat trends. The offset is likely to relate to a different calibration on the downhole sensor. The field measured electrical conductivity is considered the more reliable measurement as the portable meter is routinely calibrated each field visit.
- The LTC sensor in RN040931 was removed in December 2022. Manual water levels were measured with an electronic dipmeter during the quarterly monitoring showed a stable water level. The discrepancy between the logger water levels and the manually measured water levels is likely to be due to different reference points, and is approximately 2 cm.
- The LTC sensor in RN041243 failed in August 2022 and was replaced in January 2023. It failed again in late May 2023. There is no data available for the periods of failure.
- The Guideline does not mandate the use of water level and conductivity sensors.

Figure 4 Inacumba Gum Ridge Formation (GRF) - LTC timeseries monitoring data

Water quality monitoring

There have been no drilling or HFS activities at Inacumba.

The most recent samples available from the bores at Inacumba are from October 2022 as the pumps were removed from the bores in December 2022.

Statistical summaries of the water quality results are provided in Attachment A. In lieu of assessing potential changes to water quality associated with exploration activities, the Mann-Kendall test for trend has been performed for all analytes for each of RN040931 and RN041242. Where the Mann-Kendall test has identified a rising trend (i.e. there appears to be a deterioration in the reported water quality), a time-series chart has been prepared and the data qualitatively described in Table 4

Table 4 Inacumba - Description of timeseries data for those analytes with a rising trend

Bore in which exceedances were reported	Parameter with rising trend	Description of trend
	pH – field	The field pH was quite variable when routine sampling commenced in Jul 2019, showing an overall steeply declining trend to a minimum of 6.4. The field pH then rose to ~pH 8, where it was relatively stable, except for an anomalously low reading in September 2020. The field pH has shown a slight declining trend through 2022.
	pH - laboratory	The laboratory measured pH exhibits similar trends to the field pH. The value of the laboratory measured pH is generally approximately 0.5 pH units greater than the field measured pH. This is likely due to volatilisation of dissolved carbon dioxide, a weak acid, that is commonly observed effervescing in the groundwaters collected from the Gum Ridge Formation
	Carbonate alkalinity	Carbonate alkalinity has mostly been reported at <lor (july="" 20="" 2021="" 2021,="" 2022="" 2022)="" 3="" <lor.<="" and="" at="" august="" both="" concentrations="" except="" february="" for="" from="" in="" january="" l.="" mg="" most="" october="" one="" peaked="" recent="" sample="" samples="" td="" the="" two="" were="" where=""></lor>
RN040931 (Gum Ridge Formation) ¹	Potassium	The potassium sample collected immediately after drilling contained 22 mg/L potassium. The concentration rose from 25 mg/L to 33 mg/L as the bore continued to be sampled, and then gradually declined to 26 mg/L between January 2020 and July 2022. Most recent sample report a concentration of 28 mg/L.
	Methane (dissolved)	Dissolved methane was report <lor 20="" 2021.="" 2022="" 2022,="" 2022.<="" 5="" <lor="" a="" all="" and="" concentration="" declining="" in="" july="" l="" maximum="" may="" mg="" october="" of="" prior="" rose="" samples="" td="" the="" to=""></lor>
	Lithium (dissolved)	The dissolved lithium concentration has fluctuated between 0.4 mg/L and 0.5 mg/L except for a few lower concentration outliers. The most recent sample (0.48 mg/L) contained lower than the maximum reported concentration (0.51 mg/L).
	Molybdenum (total)	The maximum total molybdenum concentration (0.05 mg/L) was reported from the sample immediately after drilling. When routine sampling commenced, concentrations were generally 0.002 mg/L, but reduced to <lor 0.004="" 2020.="" 2021="" a="" and="" but="" concentration="" concentrations="" in="" january="" l="" less="" maximum="" may="" mg="" of="" remained="" rose="" than="" this="" to="">LOR since.</lor>
	Gross alpha	The gross alpha concentration has fluctuated between roughly 0.8 Bq/L and 1.2 Bq/L. The two most recent samples reported 1.17 Bq/L and 1.21 Bq/L in July and October 2023 respectively.
RN041242	Iron (dissolved)	The dissolved iron concentration exhibited a gradually increasing concentration from 0.14 mg/L in October 2019 to 0.38 mg/L November 2021. The May 2023 sample reported 21.9 mg/L. This sample was the first collected for six months due to the pump being removed. The most recent sample (October 2023) reported <lor. amount="" and="" bore="" collection.<="" concentration="" corrosion="" fluctuation="" in="" is="" large="" likely="" most="" of="" presence="" prior="" product="" purged="" relates="" sample="" td="" the="" to="" used=""></lor.>
(Inacumba Aquifer)	Manganese (dissolved)	The dissolved manganese concentration has risen from 0.004 mg/L in the first sample collected to a maximum of 0.574 mg/L in May 2023. The concentration has since declined to 0.288 mg/L. The rising trend is likely related to corrosion of the bore casing, with fluctuation in concentrations related to the amount the bore is used/purged prior to sample collection.
	Iron (total)	The total iron exhibits a similar trend to the dissolved iron trend, but at higher concentrations.
	Manganese (total)	The total manganese concentrations and trends are very similar to the dissolved manganese concentrations and trends.

¹ Most recent sample was from October 2022

5. Dissolved methane

Santos has analysed 313 individual samples for dissolved methane across its monitoring bores and from pastoral bores baselined and routinely monitored on Tanumbirini Station and the adjacent O.T. Downs (Beetaloo) station. This includes bore baseline and routine monitoring of pastoral water bores and Santos monitoring bores. Methane was detected in 105 of those samples (34 %). Dissolved methane has been detected in all monitored formations (Anthony Lagoon Formation, Gum Ridge Formation, Inacumba Aquifer and Proterozoic Bedrock) before and after drilling, and before and after HFS activities. The maximum reported dissolved methane concentration was 777 μ g/L, from RN037666 (a station bore) that is more than 50 km to the northeast of the Tanumbirini site, compared with a maximum reported concentration of less than 50 μ g/L at the Tanumbirini site. Methane saturation in water at atmospheric pressure is 20,700 μ g/L at 30 °C (Walker and Mallants, 2014), which is the concentration required for free gas to be present.

Timeseries data shows a rising trend in the reported dissolved methane concentrations in the Tanumbirini IMB (RN040936) and CMB (RN040930) over the period of the exploration activities. Low concentrations of dissolved methane were detected in the IMB and RN038580 prior to the commencement of drilling, however dissolved methane had not previously been detected in the CMB. The IMB reported a maximum concentration of 48 μ g/L and the CMB a maximum of 16 μ g/L. The peak concentrations were followed by a decline to local minima in July 2022 and January 2023 in the CMB and IMB respectively. The CMB concentrations returned to <LOR in samples from July and October 2022, however concentrations in that bore have since increased to 4 μ g/L. The IMB concentration increased from 15 μ g//L in January 2023 to 25 mg/L in May 2023, but has since declined to 10 μ g/L, which is similar to the pre-activity maximum of 9 μ g/L reported in December 2020. RN038580 is also at the Tanumbirini site and reported the presence of dissolved methane in 2018 (11 μ g/L). Concentrations declined through 2019 and 2020, reaching a minimum of 2 μ g/L in August 2021 (near the end of drilling). The concentration remained at 5-6 μ g/L until the last sample was collected from the bore in January 2023. A maximum concentration of 20 μ g/L (CSIRO, 2019) was reported from RN038580 prior to the commencement of drilling.

While the dissolved methane concentrations temporarily increased at the Tanumbirini exploration site, the detected dissolved methane concentrations remain less than concentrations observed elsewhere across EP161. A timeseries comparison of the methane concentrations from Santos's regular monitoring of pastoral bores and those at the Tanumbirini exploration site is shown on Figure 6 and the spatial distribution of methane concentrations from all Santos monitoring activities (including bore baselines) are shown on Figure 7. From these figures, it can be seen:

- Dissolved methane has been detected in all monitored formations (Anthony Lagoon Formation, Gum Ridge Formation, Inacumba Aquifer and Proterozoic Bedrock) before and after drilling, and before and after HFS activities.
- There is no apparent spatial pattern to the distribution of dissolved methane concentrations.
- The maximum reported dissolved methane concentration was 777 µg/L, from RN037666 (a station bore) that is more than 50 km to the northeast of the Tanumbirini exploration site.
- RN038179 (11 km southwest of the Tanumbirini site) routinely reports dissolved methane concentrations greater than 200 µg/L, with a maximum concentration of 620 µg/L reported in March 2021. CSIRO (2019) reported a concentration of 379 µg/L from RN038179 (sampled in October 2018). The methane concentration in this bore was rising when the last sample was collected in January 2023,
- RN030325 (3.6 km from Tanumbirini), RN040937 (10.8 km from Tanumbirini) and RN037654 (24.3 km from Tanumbirini) also report rising dissolved methane concentrations over the equivalent period to the drilling and HFS activities (May 2021 to February 2022), albeit at lower concentrations compared with the Tanumbirini site. The dissolved methane concentration in RN040937 has been <LOR in since July 2022 from a peak of 6 µg/L. RN030325 reported 25 µg/L in July 2023 (its most recent sample), having increased from <LOR in May 2022.

- RN037665 reported a dissolved methane concentration of 53 μg/L in May 2023. Its previously reported maximum concentration was 13 μg/L, reported in May 2018, with intervening concentrations less than or equal to 3 μg/L. RN037665 is approximately 30 km from the Tanumbirini site.
- RN040938 reported an increasing trend from <LOR to a peak of 37 μg/L in May 2021, followed by a gradual decrease to 1 μg/L in October 2022 (most recent sample)
- RN033761 reported an increasing trend from <LOR to a peak of 30 μg/L, followed by a decrease to less than 10 μg/L in the following two samples. From March 2021 the reported concentration increased to 10 μg/L in May 2022, and was reported to be 24 μg/L in July 2022, but was <LOR in May and July 2023.
- RN040931 (the GRF monitoring bore at Inacumba) reported 5 µg/L in May 2022 and 2 µg/L in July 2022. All other samples prior to and post these dates, the reported dissolved methane concentrations were <LOR.
- RN035502 reported 1 µg/L in July 2023 with all previous results reporting <LOR.
- Of the bores that are routinely sampled by Santos, only six bores have never reported dissolved methane greater than the limit of reporting (RN040939, RN041242, RN025291, RN033608).
- Dissolved methane concentrations may reduce to less than the limit of reporting, and then increase again. These changes may occur between consecutive samples (every three or six months depending on the bore) or over a longer period.

CSIRO (2019) collected 25 samples for dissolved methane in October to November 2018. The CSIRO (2019) limit of reporting was $0.2 \mu g/L$ as compared with the $1 \mu g/L$ at which Santos's results are usually reported. CSIRO reported the presence of methane in all the samples it collected. It found that concentrations were generally less than 10 $\mu g/L$, but concentrations up to 1129.5 $\mu g/L$ were present. Stable isotope composition of the methane in the two samples analysed (RN031397 and RN038179) indicated that the presence of methane was due to microbial activity. RN038179 is on Tanumbirini Station and is included in the Santos regional monitoring program. CSIRO (2020) identified that methanogenic organisms (i.e. methane producing organisms) are naturally occurring within the groundwater of the Cambrian Limestone Aquifer. Dissolved methane concentrations are generally too low to enable isotopic characterisation. CSIRO has advised Santos that analysis to determine the stable isotope composition of the methane, which would confirm whether the methane is sourced from microbial activity, cannot be performed with confidence in the results if the dissolved methane concentration is less than 500 $\mu g/L$ (pers. Comm. Santos, 2022).

No propane or ethane has been detected in any of the groundwater samples collected by Santos. While the absence of propane and ethane does not preclude a thermogenic origin for the methane, it does indicate that a biogenic source to the methane detected is more likely.

* the graphs report the same data at different scales, except for the lowermost graph where some bores have been removed for clarity
